**********BREAKTHROUGH_
+ Therefore, if we compared the genome of Cancerous (e.g. HeLa) cells and Healthy cells; we my be able to isolate the genetic code that is responsible for Telomere length reduction.
++ In such isolated genetic code, then, we look for occurrences of the hypothesized Counter that Healthy cells use to decay._
+ Equilibrium: Perhaps what is needed is not endless cellular division (Cancer) or declining cellular division (Senescence); but EQUILIBRIUM between these two situations!!!!
++ To achieve Equilibrium, an mRNA 'vaccine' containing Cancer DNA could be injected in an aging person (Healthy Cells)._
+++********** The code an 'mRNA' vaccine should pass to Healthy Cells is that they should only die IF they become cancerous._ This is equilibrium._
****
++++ Currently Cellular Senescence occurs regardless of whether the cell is Cancerous (dividing unlimitedly) and Cancers multiply indefinitely, inspite of being sick._
++++********** How do we identify if a cell has become Cancerous?
+++++ Simply, if Telomere length EXCEEDS a certain critical number, we execute the foregoing "if" statement._**********
+++++ Presently, the IF statement is non-existent and Healthy (non-Cancerous) Cells' Telomere length keeps reducing each iteration._
+ The ideal occurrences of TTAGGG in a person according to my study is 9000. Young people have these many occurrences.
++++++ It is my theory that the repeating occurrences of TTAGGG comprising Telomere length is actually the count: this sequence represents the digit "1" and by repeating it; the body is actually COUNTING._ THEREFORE, all our mRNA Vaccine "IF" statement has to say is:
++++++ **********

DO {
# In case cell is cancerous
IF occurrences of "TTAGGG" in Cell Chromosomal DNA > 15000
Call SenescenceFunction()

Reset in case cell is dying
ELSEIF occurrences of "TTAGGG" in Cell Chromosomal DNA < 3000
Call ActivateTelomerase()
}
WHILE count(TTAGGG) in Cell Chromosomal DNA > Zero

SenescenceFunction() {
# Initialize aging process
Delete 6000x "TTAGGG" from Cell Chromosomal DNA
Where preceding GENETIC CODE is "TTAGGG"
And succeeding GENETIC CODE is "TTAGGG"
}

ActivateTelomerase() {
#Effect Telomerase repairs of DNA
Append 6000x "TTAGGG" in Cell Chromosomal DNA
Where preceding GENETIC CODE is "TTAGGG"
And succeeding GENETIC CODE is "TTAGGG".
}**********
